

multiple organ dysfunction syndrome (MODS), systematic inflammatory response syndrome (SIRS), sepsis, fat embolism, morbidity and mortality in patients admitted with poly-trauma.

Method: CENTRAL, MEDLINE 1950 – present, EMBASE 1980 – 2015 and AMED (1985 to 2015) were searched for the relevant papers. Studies written in English language, which compared the timing effect of the orthopaedic intervention (Early vs. Delayed), on the aforementioned complications in patients with poly-trauma, were included.

Result: 7 studies met the inclusion criteria encompassing a total of 3,461 participants. 2 studies advocated early intervention compared to 5 studies supporting the use of damage control orthopaedics and delaying the timing of surgery for > 24 hrs (Delayed intervention). The complication rates varied across the studies for each intervention category. Nevertheless, the mortality rate was higher with the delayed intervention in 6 of the 7 studies.

Conclusion: It appears that delaying the definitive orthopaedic surgical intervention is the more popular choice due to the reduced complication rates, compared to early interventions. Nevertheless, our findings cannot validate such approach, as the appropriate intervention could be case dependent.

1237: TRENDS IN DISCHARGE LOCATIONS FOR PATIENTS POST HIP FRACTURES: A 10 YEAR EXPERIENCE FROM AN IRISH TRAUMA CENTRE

E. Coveney*, J. Quinlan, M. Cleary. *University Hospital Waterford, Waterford City, Ireland.*

Introduction: With the introduction of the Irish governments Nursing Home Support Scheme in 2009 we set out to assess if there has been a decrease in patients being discharged to nursing homes after hip fractures and compare our rates with national rates.

Aim: Assess trends in discharge destination for all hip fractures over a 10 year period.

Method: Data acquisition from hospital registry for all hip fractures presenting to our institution from 2005–2015 and from the National Hip Fracture Database from 2013. Patients were categorised by age, sex, pre-admission location and length of inpatient stay. Annual rates of patient being discharge to nursing homes was accumulated and comparison made with national rates.

Result: A total of 4,395 patients were admitted with or who subsequently developed a hip fracture, from January 2005 until September 2015. 1019 were discharged to nursing homes and long stay facilities. Annual figures show that there has been a decline in patients being transferred to long term care facilities.

Conclusion: Since inception of Nursing Home Support Scheme, there are annually, fewer patients transferring to nursing home care. Future projections should further invest in rehabilitation and home support services for patients.

1262: INAPPROPRIATE MEASUREMENT OF POSTOPERATIVE C-REACTIVE PROTEIN IN TRAUMA AND ORTHOPAEDIC SURGERY: A QUALITY IMPROVEMENT PROJECT

J. Glasbey*, L. Galloway, R. Whitham, S. Parker, O. Blocker, A. Ghandour. *Department of Trauma & Orthopaedic Surgery, Cardiff, UK.*

Aim: Measurement of early postoperative CRP is inappropriate where infection is not suspected. This quality improvement project aimed to reduce the cost of inappropriate early postoperative CRP testing at a busy major trauma centre.

Method: Retrospective audit. All adult general trauma patients, and elective patients undergoing hip or knee primary arthroplasty in May 2015 were included. Hand and foot surgery, and patients with a pre-operative

leucocytosis were excluded. CRP was collected at three time points; post-operative days 1,2 and 3.

Result: 65 elective and 122 trauma patients were included (mean age=64.8y, range=18-98). CRP was measured in 90 (48%) postoperative patients; 24 (37%) elective cases and 66 (54%) trauma cases. A total of 118 tests were requested between postoperative days 1 and 3. Only 24 of the 90 patients tested had >1 CRP to monitor a trend. At a cost of £3.29 per test, our department spends £388/month or £4658/year on inappropriate testing. Extrapolated to the Welsh deanery, there is a cost-saving potential of £160,205 in elective, and over £300,000 in trauma settings.

Conclusion: Early postoperative CRP testing is common, and may mislead clinical judgement. Avoiding inappropriate postoperative CRP testing in general trauma patients has a small, but significant economic benefit.

1327: CRITIQUING OPERATIVE FRACTURE FIXATION: THE DEVELOPMENT OF AN ASSESSMENT TOOL

D. Hawkes*, J. Harrison. *Orthopaedic Department, Countess of Chester Hospital, Chester, UK.*

Introduction: A tool for formally assessing operative fracture fixation would provide a framework for orthopaedic surgeons to plan procedures, enable feedback on the technical aspects of surgery to be provided and thereby assist in development and training. It could also be used remotely to allow distant mentoring. The aim of this work was to develop a tool and undertake reliability and validity assessments.

Method: The developed tool comprises of 4 questions which reflect AO principles (pertaining fracture reduction, stability, implants used and overall surgical impression). Ten orthopaedic consultants were selected as reviewers and completed the assessment of 20 cases using an online webpage. Inter-observer reliability and content validity were assessed by accepted means.

Result: Average measure inter-class correlation coefficients ranged from 0.91–0.92. A Cronbach's Alpha of 0.97 indicated excellent internal consistency. A content validity ratio of 0.65 indicated the expert reviews considered the tool valid.

Discussion: The results of this initial work are promising. Further evaluation will assess intra-assessor reliability. A smartphone application will be developed to enable the tool to be introduced for use in Africa as part of the AO Alliance Foundation with the aim of assisting in surgeon training.

1351: A REVIEW OF FUNCTIONAL OUTCOMES AND UNION RATES IN PATIENTS WITH LATERAL CLAVICULAR FRACTURES TREATED WITH HOOK PLATE FIXATION

T.C. Edwards, B. Patel, H. Brandford-White, D. Banfield, D. Woods, A. Thayaparan, T. Grove*. *Great Western Hospital, Swindon, UK.*

Introduction: Clavicular hook plates have been used over the last decade in the treatment of lateral clavicular fractures with good rates of union reported throughout the literature. Fewer studies have reported the functional outcome. We aimed to review the functional outcomes.

Method: 21 patients were included with Neer II & III fractures treated with hook plates between March 2010 and February 2015. Patients were followed up post plate removal and evaluated clinically using the Oxford Shoulder Score. Their post plate radiographs were assessed by an independent radiologist and bony union documented.

Result: Mean age was 40 (range 14–63) with a male: female ratio of 17: 4. Mean follow up was 5 months post injury (1–26). The hook plate remained for a mean time of 4.3 months (2–16). One patient developed a post-operative wound infection treated with antibiotics, 2 patients developed adhesive capsulitis, one patient had not achieved bony union prior to hook plate removal at 16 months, two patients required revision. All patients
